Final Year Project

Performance Analysis of Design Patterns in Microservice Architecture

Rajit Banerjee

Student ID: 18202817

A thesis submitted in part fulfilment of the degree of

BSc. (Hons.) in Computer Science with Data Science

Supervisor: Professor John Murphy

UCD School of Computer Science
University College Dublin
October 26, 2021

Chapter 1: Project Specification

1.1 Problem Statement

Microservice architecture is a style of designing software systems to be highly maintainable, scalable, loosely-coupled and independently deployable. Moreover, each service is built to be self-contained and implement a single business capability. Design patterns in software engineering refer to any general, repeatable or reusable solution [1] to recurring problems faced during the software design process. The aim of this project is to analyse the performance of a number of microservice design patterns (based on metrics such as query response time, CPU/RAM usage, cost of hosting and packet loss rate), and evaluate their benefits and shortcomings depending on the business requirement and use case. A non-exhaustive list of design patterns that could be explored is as follows:

- API Gateway
- Chain of Responsibility
- Asynchronous Messaging
- Database or Shared Data
- Event Sourcing
- Command Query Responsibility Segregation (CQRS)
- Saga
- Circuit Breaker
- Strangler (Decomposition)
- Consumer-Driver Contract Test
- Externalise Configuration
- Aggregator
- Branch

For the aforementioned design patterns, sufficiently complex simulations will be designed for the performance engineering experiments. The project will also look at some common issues in microservices, and how they compare with traditional monolithic architectures.

1.2 Background

Microservices have gained traction in recent years with the rise of Agile software development and a DevOps [2] approach. As software engineers migrate from monoliths to microservices, it is important to make appropriate choices for system design and avoid "anti-patterns". Although no one design pattern can be called the "best", the performance of systems can be optimised by following design patterns suited to the use case, with the right configuration of hardware resources.

1.3 Related Work

Due to their popularity, microservices have been written about extensively in books like [3], [4], [5]. Articles such as [6], [7], [8], [9], [10] discuss the intricacies of microservice architecture as well as the trade-offs between various common design patterns. In [11], the performance problems inherent to microservices are explored, with evaluations performed using a custom-built prototyping suite. Akbulut and Perros [12] dive into the performance analysis aspect of microservices that is being proposed in this project, where they consider 3 different design patterns.

1.4 Datasets

Any data that is to be used or analysed in this project will be generated during the course of experiments. There are no dependencies on additional datasets.

1.5 Resources Required

A non-exhaustive list of resources is specified below, following preliminary needs assessment.

• Languages/Frameworks: Node.js + Express.js, React.js

• Tools: Git, Docker, Apache JMeter

• Database: MongoDB

 Compute: Linux server (maintained by the UCD School of Computer Science), possibly a High-Performance Computing Cluster
